

Noah Product Vision

State: July 2026. Internal working document.

1. The vision

Noah becomes a digital transformation operating system that runs autonomously. The target user is the operations VP or the CEO. The alternative they are choosing against is hiring an expensive consultancy or standing up a large internal transformation team.

An important caveat sits underneath that statement. This is not our sales pitch today. We currently sell to transformation managers, not to CEOs, so our commercial angle stays where it is. We keep positioning Noah as the replacement for expensive consultants. The point of the vision is directional. If we build it properly, the value moves up the organisation on its own, and the CEO conversation follows rather than being forced.

2. What the product should actually do

The vision breaks into six capabilities. Together they form one loop, from understanding a business to running live systems inside it.

2.1 Relevant market insights

Noah brings in external signal. That means news, regulatory movement, and real world examples of what comparable organisations are doing. The value is not the feed itself. The value is the interpretation. For every relevant signal, Noah explains the likely impact on this specific organisation and how the user can turn it into an advantage. The output is a judgement, not a link.

2.2 Relevant business insights

This is the discovery system we already run. We interview employees, we surface opportunities, and we generate business cases and process descriptions from what we hear.

The expansion is one of scope. Today we work at team level. We want to interview department by department and then stitch the results together into a single map of processes and insights across the whole organisation. That map is the asset. It shows where work actually flows, where it breaks, and where the same problem appears in three places under three different names.

2.3 Executive tasks

Once we have insight, someone has to prepare the organisation to act on it.

Further exploration. We are testing a first version of the assumption register. It finds the blind spots in our own recommendations, then takes follow up actions to resolve them. The system asks what it does not yet know, goes and gathers that information, and makes the recommendation solid rather than plausible.

Preparation. We recently launched team wide interviewing that places each person on the Moore innovation curve. A manager can then see who is likely to champion a new project and who will need to be brought along. This is the first of a set of preparation features. The goal is to cover every piece of groundwork that has to happen before a proof of concept starts.

PoC creation. We are building an in house coding agent. It has a direct job, which is to build features for us. It also has a second job, which is to prove out what an enterprise grade agent can and cannot do. If it holds up, we ship a version that builds a proof of concept for the client team directly, so the idea can be tested in the real environment instead of argued about in a slide deck.

2.4 Running experiments

Once a proof of concept is live, we need to know whether it works. Noah runs the experiment in two tracks.

The first track is quantitative. We integrate Noah with the proof of concept and with the systems it touches, so we can measure real numbers rather than estimated ones.

The second track is qualitative. We run another round of interviews with the team. Does the system perform in their eyes, and what needs to change. If the organisation decides to go further, that feedback is passed automatically into the integration stage and shapes the final build.

2.5 Integration

When an experiment succeeds, Noah helps carry it into production. Humans lead this stage. Noah does the coordination work around them.

- **Roadmap.** Noah generates the implementation roadmap.
- **Tickets.** Noah writes tickets into the ticketing system the organisation already uses, derived from that roadmap.
- **Communication.** Noah handles the running communication with the internal and external teams doing the final build. Feeding updates back to the user.

2.6 Manage and control

The last step closes the loop. Once a system is live, Noah tracks its performance over time and checks that it keeps doing what it was supposed to do. This is what turns Noah from a project tool into a permanent system of record for transformation.

3. Design principle

Every part of the product needs a visual interface for working with the gathered data and insights. That is not in question. But the agent is the centre of the product, not the screens. Noah should feel like something you give orders to. The user states an intent, the agent acts, and the interface is where you inspect and steer the result. If the product ends up feeling like a

dashboard with an assistant bolted on, we have built the wrong thing.

4. Priorities

Deadline: 31 August

1. Validate this approach with stakeholders, existing clients, and subject matter experts. This comes first, because everything below assumes the direction is right.
2. Build the internal version of the coding agent and evaluate how it performs.
3. Improve the assumption model, and improve the mapping from team level insight to organisation level insight.

5. Target for end of year

By the end of the year we should have a working version of every part of the loop. It does not need to be good. It needs to exist, end to end, at a quality we can put in front of alpha testers. Breadth first, then depth.
